## Working principle

The M21 flowmeter is a metal tube variable area flowmeter for low flows.

It is based in the principle of variable area, which is obtained by a float that moves up and down inside a calibrated orifice. The force from the fluid displaces the float until it reaches an equilibrium point.

Each float position corresponds to a flow rate value. The float magnetic field moves the needle inside the housing by means of magnetic coupling to the corresponding flow rate point on a graduated scale.

Ao= Calibrated orifice area  
Af= Float area  
Pf= Weight of the float  
E= Force of the fluid flow  
Al= Ao-Af= Free area of flow

### Constant flow regulators RCA / RCD

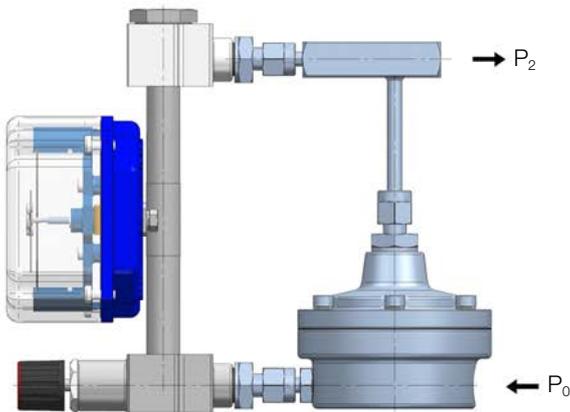

The M21 flowmeters are designed to incorporate the RCA and RCD constant flow regulators, which can make flow rate to be constant when inlet or outlet pressures are variable.

In gas applications, RCA model is used when inlet pressure is variable and outlet pressure or counterpressure is constant; RCD model is used in installations where inlet pressure is constant and outlet pressure or counterpressure is variable.

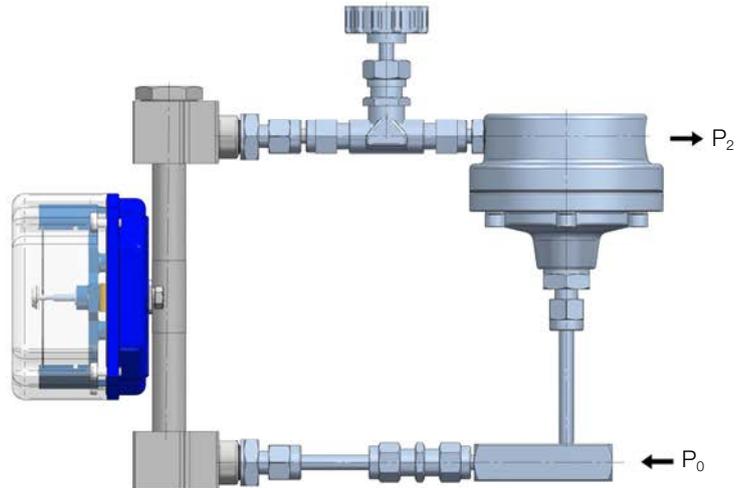

In applications for liquids RCA model is used in all cases.

The differential pressure between  $P_0$  and  $P_2$  must always be higher than 350-450 mbar depending on the model. This is necessary to guarantee a correct performance of the flow regulator.

RCD (use with models M21-HR, M21-HN)
